MetsäWood

1 Kerto-Q – benefits

- Kerto-Q products can be used to brace buildings of different sizes, regardless of the frame material.
- The large production dimensions of Kerto-Q products improve installation efficiency by reducing the amount of lifting required on the construction site.
- Kerto-Q products are available globally.
- Kerto-Q products can be sawn according to the dimensions of the construction project. In many cases, this eliminates on-site waste completely.
- Kerto-Q products are easy to design using Finnwood® software.
- In addition to construction, Kerto-Q products are suitable for industrial applications that require dimensional stability, lightweight and strength.
- Using Kerto-Q products enhances efficiency and is part of modern timber construction.

Kerto® laminated veneer lumber (LVL) is a product made of bonded softwood veneers for use as structural or non-structural elements in buildings and bridges. The thickness of Kerto-Q varies from 21-75 mm; other dimensions vary according to customer requirements. The product is manufactured mainly from spruce veneers, but small part of the veneers may also be pine. The nominal thickness of the veneers is 3 mm and they are bonded together using phenol formaldehyde adhesive suitable for exterior use. About one fifth of the veneers in Kerto-Q are cross grained.

Figure 1: Metsä Wood's Kerto® products – quality for builders and industrial applications.

Figure 2: Versatile use of Kerto-Q panels in floors and walls.

2 Kerto-Q for all wooden structures

Kerto-Q is a load-bearing panel product that can be used in both horizontal and vertical structures. About one fifth of the veneers are crosswise to the surface veneer, which enhances the transverse strength and stiffness of the panel. Kerto-Q can be sawn according to the customer's dimensions, without having to take into account the ratio between the height and width of the beam structures, for example. Apart from the maximum dimensions, Kerto-Q panels have no standard sizes - they are manufactured according to the customer requirements.

The thickness range of the Kerto-Q panels is 21-75 mm. Standard thicknesses are available at intervals of 3 mm up to 33 mm, and at intervals of 6 mm for thicker panels. The surfaces of Kerto-Q panels can be optically sanded to enhance their appearance or calibrated to a specific thickness with an accuracy of ± 0.5 mm. The maximum sizes of Kerto-Q panels are 2.5 m x 20 m and 1.8 m x 25 m. Local transport restrictions may limit the maximum size. Untreated Kerto LVL has reaction to fire class D-s1,d0.

Kerto-Q is suitable for the most challenging wooden structures, and it can be glued together to create composite structures and elements to serve as a load-bearing member or as a beam to transfer horizontal and vertical loads. Holes and notches machined in the Kerto-Q structures only have limited reduction to the load-bearing capacity. The edges of the panels can be profiled to create diaphragms and prevent displacement differences at panel joints. Kerto LVL is suitable for use in service classes 1 and 2, and with an additional protective treatment in service class 3. Protective treatment is outside of the scope of VTT certificate.

Kerto-Q products can be machined using normal woodworking tools. In addition, Kerto-Q can be treated against weather and mould, and it can be coated with paints or varnishes. Kerto-Q products do not require pre-drilling for fastening as their characteristic density is 480 kg/m^3 . The need for pre-drilling comes only from the fastener requirements. For example, large screws and nails, as well as all bolts and dowels, require pre-drilling.

Figure 3: Kerto-Q panels with thicknesses of 33 mm, 45 mm and 69 mm.

Figure 4: Kurpark Wuellpavillon (Bode Petters Architekten) in Germany uses Kerto-Q in radial rafters and wall columns. Photo: Hanns Joosten.

3 Kerto-Qp – a stiff and tall beam

Kerto-Qp is a dimensionally stable beam suitable for roof and intermediate floor structures in both new constructions and renovation projects. The structural height of Kerto-Qp beams allow spacious interiors while reducing the amount of supporting structures. An insulation layer with a thickness of around 500 mm can be installed between the tall beams to achieve excellent thermal resistance of the structure. With dimension of $42 \text{ mm} \times 500 \text{ mm}$, $51 \text{ mm} \times 620 \text{ mm}$ and $63 \text{ mm} \times 830 \text{ mm}$, the Kerto-Qp beam is suitable for horizontal spans of up to 14 m, with a centre-to-centre spacing of 1200 mm. Shorter centre-to-centre spacing between the beams allow horizontal spans up to approximately 18 m.

Kerto-Qp beams have a unique structure and are manufactured taller and thinner than Kerto-S beams. Kerto-Qp beams also have better strength and stiffness properties than Kerto-Q, which allow more cost-effective construction. The crosswise veneers in the structure, for example, minimise moisture deformations.

^{*)} Other National Annexes may give different results.

Note! The preliminary design table does not replace project-specific structural design by a qualified person.

4 Horizontal structures and overhangs

Kerto-Q panels are suitable for horizontal load-bearing panel structures in roofs and intermediate floors. Using thicker panels allows longer spans between supports. In roof structures, Kerto-Q panels form a durable base for roofing. MouldGuard treated panels are recommended to be used in unheated spaces to reduce the risk of mould growth. Preliminary design Tables 2-5 give different panel thicknesses as well as permanent and snow loads for single and multi-span panels both perpendicular and parallel to the supports. The preliminary design tables do not replace project-specific structural design by a qualified person.

Due to its excellent strength properties, Kerto-Q panels can be used in thin roof line overhangs as a load-bearing structure without the need of separate supports. The corner overhangs can also be built without additional supports.

In intermediate floor structures, Kerto-Q panels enable sparser frame spacing and strong and stiff floor panelling. The properties of Kerto-Q can also be utilised when designing frames for buildings. For example, Kerto-Q flooring can be used as horizontal bracing, which can usually replace separate bracing structures. The large panel size of Kerto-Q allows faster installation of large areas with less lifting. Using a panel size of 2.4 m x 10 m, for instance, an intermediate floor of 9.6 m x 10 m can be installed using only four panels. The panels may be single or multi spanned depending on the frame spacing. Preliminary design Tables 6-9 give different panel thicknesses as well as permanent and imposed loads for single and multi-span panels, both perpendicular and parallel to the supports.

Kerto-Q panels can be used in unique applications, such as warehouse shelves and industrial solutions, since the panels are lightweight and easy to replace.

^{*)} Other National Annexes may give different results.

Figure 11: Multi-span Kerto-Q panel. The face veneer grain direction of the panel in relation to the load-bearing frame. On the left, the span is parallel and on the right, perpendicular.

4.1 Point loaded panels

Kerto-Q panels have good resistance against concentrated loads. The concentrated loads determine a minimum panel thickness against the local effects on structures. Table 10 present the maximum concentrated load for a given panel thicknesses and support spacing.

Table 10: Preliminary design table for a floor panel for different Kerto-Q thicknesses and point loads (50x50 mm²). The panel is supported by continuous supports from all edges. EN 1995-1-1 + NA:FI^{*)}, service class 1, CC1, load categories (residential A, office B and congregated C). Deflection limits $w_{net,fin} \leq \min(L/100; 6 \text{ mm})$. Values are valid also for optically sanded products.

*) Other National Annexes may give different results.

4.2 Eaves and roofs overhangs

Roof overhangs and eaves made of Kerto-Q panels are thin and elegant structures. The underside of eave panels may be custom designed and coated with paint or varnish. Additional elements, such as decorative wooden elements, can easily be fastened underneath of the panels. The maximum width of roof overhangs and eaves depends on the installation direction and the thickness of the panel. When designing and installing panels, it must be taken into account that the panels have different load-bearing capacity depending on the grain direction of the face veneer.

The panels can be machined and surface treated at the mill, which significantly increases installation speed on-site (see Chapter 11 for information on available surface treatments). Roof panels provide a good slip resistant working platform as soon as they are fastened to the supports. The panels can be fastened to timber, concrete or a steel frame. The wide range of dimensions enable an optimal solution for each application. Panel structures are suitable for both flat and pitched roofs regardless of the roof slope.

Structural designs should specify the number and type of fasteners required. Panel fastening must also be designed to withstand the upward wind effect. When needed, an installation plan should be prepared that indicates, for example, the installation order.

Tables 11 and 12 present roof overhang lengths for Kerto-Q panels with different thicknesses and surface, and snow loads. The face veneer grain direction of the panel in relation to the overhang direction is presented in Figure 12. The field span length of the overhanging panel should be at least L_c and at most $2x L_c$.

Table 11: Preliminary design table for overhang width L_c for different Kerto-Q thicknesses and loads. The panel is supported by continuous supports according to Figure 13. EN 1995-1-1 + NA:FI^{*)}, service class 2. Point loads not taken into account. Deflection limit for overhang $w_{net,fin} \leq L/75$ and for field $w_{net,fin} \leq L/150$. Roof slope is not limited.

Figure 12: The face veneer grain direction of the panel in relation to the overhang direction. On the left, the projection is perpendicular and on the right, parallel.

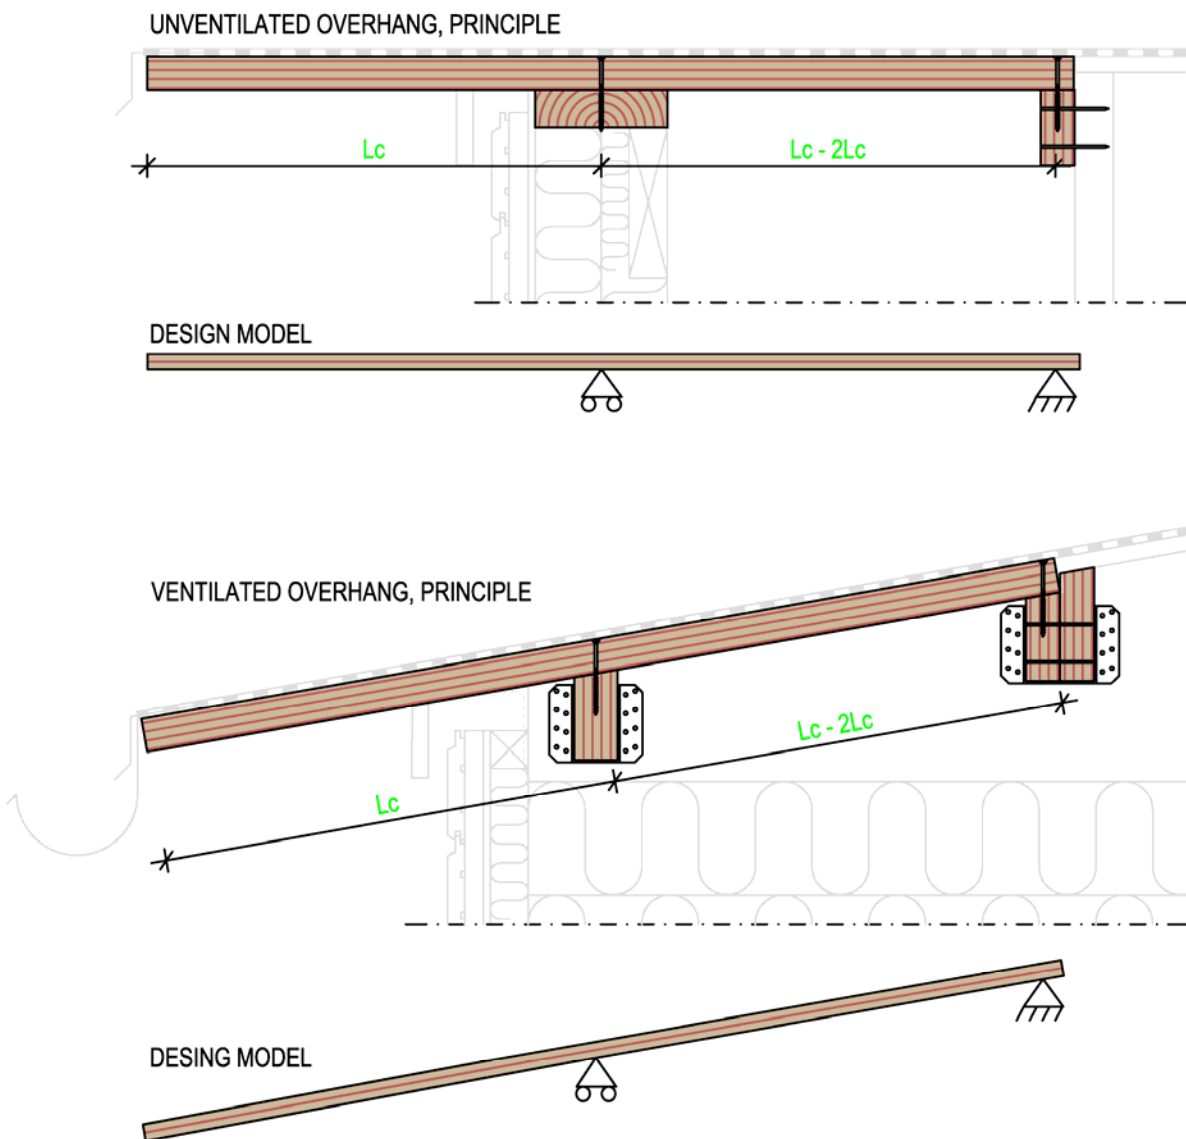

Figure 13: Principles of overhang solutions; overhang widths L_c for various panel thicknesses are presented in Tables 11 and 12. Field span length at least L_c and at most $2x L_c$.

4.3 Corner overhang

The use of Kerto-Q as overhangs is described above. Overhangs without supporting beams for the whole overhang area including corner overhangs, need to be buildable with Kerto-Q panels. Table 13 presents roof corner overhang lengths for Kerto-Q panels with different thicknesses and permanent and snow loads. The face veneer grain direction of the panel in relation to the overhang direction is presented in Figure 14. The panel is supported with continuous support according to Figure 13.

Table 13: Preliminary design table for corner overhang width L_c [mm] for different Kerto-Q thicknesses and loads. EN 1995-1-1 + NA:FI^{*)}, service class 2. Point loads not taken into account. The surface veneer grain direction can be in either overhang direction. Deflection limit $w_{net,fin}$ for overhang L_c is $L/75$ and for corner overhang $\sqrt{2} \cdot L/75$. Roof slope is not limited.

| Surface structure | g_2 [kN/m ²] | 0.20 | | | | | 0.60 | | | | |
|-------------------------|----------------------------|----------------------|---------------------------|------|------|------|--------------|------|------|------|------|
| Snow load on the ground | s_0 [kN/m ²] | 1.00 | 1.60 | 2.00 | 2.75 | 3.50 | 1.00 | 1.60 | 2.00 | 2.75 | 3.50 |
| Snow load on the roof | s [kN/m ²] | 0.80 | 1.28 | 1.60 | 2.20 | 2.80 | 0.80 | 1.28 | 1.60 | 2.20 | 2.80 |
| Wind load | w [kN/m ²] | 0.60 / -1.20 | | | | | 0.60 / -1.20 | | | | |
| Maintenance load | q_H [kN/m ²] | 0.40 | | | | | 0.40 | | | | |

Figure 17: Principle of Kerto-Q corner overhang.

Figure 18: Principle of Kerto-Q corner overhang.

4.4 Panel joint types

The following joint types can be used to connect Kerto-Q panels. The actual structural load-bearing capacity depends on the project, and must be checked separately in every individual case. More information of the minimum dimensions for nailed or screwed connections can be found from Chapter 10.1.1. For connector positioning, the acting force direction is parallel to the joint. If the force direction is perpendicular to the joint, information on the connector positioning can be found from the Kerto Manual connection cards.

Structurally supported panel joints

Panels may be supported using structural supports as presented in Figure 19. The panel edges in these joints are usually non-machined and the force acting parallel to the joint is transferred through the load-bearing structure from one panel to the next. The diameter, spacing and insertion depths of the fasteners should be according to the structural design.

Figure 19: Panel joint on wooden construction, for minimum spacing see chapter 10.1.1.

Self-supported panel joints

The edge of the panel can be machined for self-supporting panel joints (see Figures 20 and 21). Usually, they form a half-lap connection where part of the panel thickness is machined to create matching pairs of the edges. The diameter, spacing and insertion depths of the fasteners should be according to the structural design.

Figure 20: Joint with half lap, for minimum spacing see chapter 10.1.1.

Figure 21: Joint with half lap and seam piece, for minimum spacing see chapter 10.1.1.

5 Panel bracing

All building frames need bracing that transfer horizontal loads, such as wind load, to the foundations. In most buildings, panel bracing is used. Kerto-Q is an ideal product for panel bracing in various types of buildings as it is easy to fasten to most materials. The thicknesses of Kerto-Q are greater than those of commonly used wood-based panels. This allows sparser frame spacing than normal without the risk of bracing panel buckling. When Kerto-Q panels are used for bracing, additional bracing systems are not usually needed.

Kerto-Q panels are suitable for both horizontal and vertical bracing. Horizontal bracing panels transfer horizontal loads to the vertical bracing panels; the vertical bracing panels in turn transfer forces downwards. Preliminary design values for fastening bracing panels are presented in Chapter 10.1.1.

In addition to bracing the buildings, Kerto-Q panels can be designed to act as a load-bearing member that transfers vertical loads, thus removing the need for a separate load-bearing frame structure. In walls and roofs of conventional buildings, Kerto-Q panels can also be utilised as a water vapour and air barrier, in which case no separate barrier layer is needed. The fire behaviour of Kerto-Q is highly predictable, which makes it a suitable bracing panel also for situations such as fire.

Figure 22: A hall braced with Kerto-Q panels.

6 Columns

Kerto-Q columns can be used as combined members suitable for transferring vertical loads in various structures. When using built-up columns in a framed structure, it is possible to use timber-to-timber connections between the members without using separate steel parts. The crosswise veneers in Kerto-Q panels provide good connection strength, and usually there is no risk of cracking in typical corner connections. For example, Kerto-Q columns can be used in three-hinged frames and, depending on the width of the frame, the rafters are either Kerto-S or glulam.

A column in a three-hinged frame consists of two or more Kerto-Q panels. An intermediate piece is installed between the panels to form a box structure. The thickness of the intermediate piece is advisable to be the same as the width of the rafter, in which case the rafter can be installed between the Kerto-Q panels. When choosing the dimensions of the column, it is worth noting that Kerto-Q panels and Kerto-S rafters can be sawn into a single tapered shape. In this case, the cross-section of the column can be smaller at the level of the foundations than at the level of the bending resistant connection. The most cost-effective option is to choose a tapered shape that utilizes the maximum panel width. For example, a column with a smaller width of 600 mm and a larger width of 1200 mm equals 1800 mm, which is the production line width at the Kerto mill in Lohja (see Figure 23).

Figure 23: Principle of optimal sawing of single tapered beams.

Figure 24: Built-up columns made of Kerto-Q are used in three-hinged frames.

Figure 25: A box column made of two Kerto-Q panels.

Figure 26: A rafter installed between the Kerto-Q members and connected with bolts.

When a rafter is installed between the two Kerto-Q members of a column, the corner connection can be designed according to the instructions of the timber-to-timber connections. Commonly available fasteners, such as bolts, dowels, screws or nails, are suitable for the connection. Fasteners are chosen according to the loads affecting the bending resistant connection. Nails can be used for smaller loads while screws, dowels and bolts are used for higher loads.

7 Holes, notches and free-shaped beams

Due to its crosswise veneers, Kerto-Q is suitable for use as a beam with holes or notches. The crosswise veneers distribute the load perpendicular to the face veneer grain direction while reinforcing the structure of the beam. The size of a notch can even cover the entire beam and thus give shape to the whole structure.

Maximum hole size 70% of the beam height

It is possible to make round or rectangular holes in Kerto beams. The maximum diameter for a circular hole is 70% of the beam height. The maximum height of a rectangular hole is 30% of the beams height. Holes should be positioned along the centre line of the beam. If the position differs from the centre line, additional limitations are given. The Kerto product certificate provides design instructions that are in line with standard EN 1995-1-1 for determining the shear and bending capacity of a beam with holes. The effect of an individual hole on the deflection of the beam is minor and does not need to be taken into account. In the case of multiple holes, the effect on the deflection should be considered.

Figure 27: Ventilation channels and water pipes in an intermediate floor made of Kerto.

Figure 28: Holes in the beams of a floor element.

Figure 29: Holes in a Kerto-Q panel.

Load-bearing notch

Kerto-Q beams can be machined to include various types of notches and chamfers. The most typical is a notch at the end the beam. If notches in a beam are located on the side of the support, the shear capacity of the beam decreases as a result of cracking in the grain direction. Kerto-Q beams are well resistant to cracking, meaning the design shear capacity is usually close to the shear capacity of the residual cross-section.

Figure 30: Kerto-Q beams notched on the side of the support.

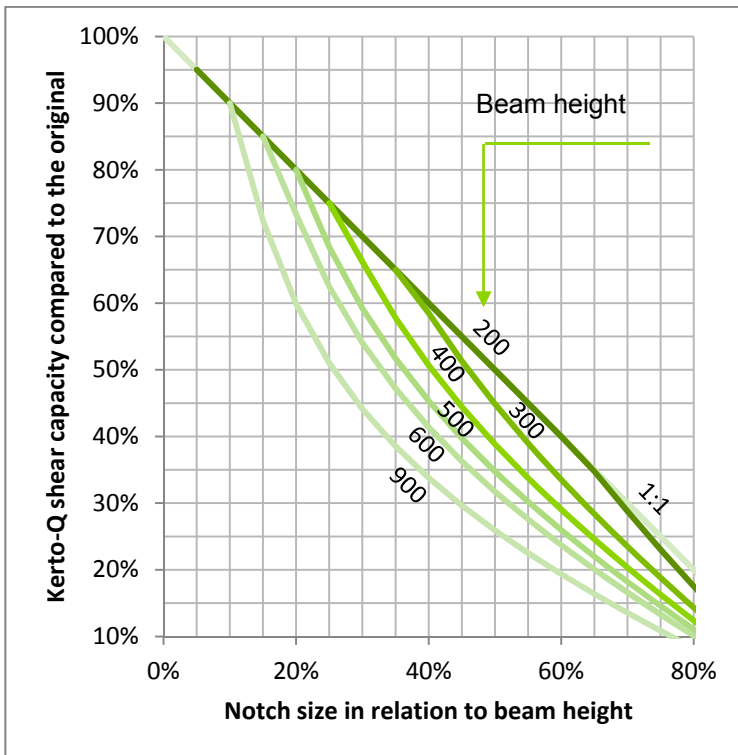

Figure 31: Shear capacity of a notched Kerto-Q beam.

- Notched Kerto-Q beams can be designed edgewise in accordance with standard EN 1995-1-1 and the VTT-C-184-03 certificate.
- In the design table, $x = 0.5h$ and $i = 0$ meaning the notch is vertical.
- $k_n = 16$ for edgewise Kerto-Q
- The decrease of shear capacity for beams with a notch on the side of the support is presented for various beam heights.
- 1:1 indicates the decrease of shear capacity for beams with a notch at the opposite side of the support.

Figure 32: Notched end of a beam. Source: EN 1995-1-1, Figure 6.11.

Free-shaped member allow unlimited shape for buildings

The entire Kerto-Q beam can be machined to curved, pitched cambered, double tapered or free-shaped members. Shaped members are manufactured by cutting the required shape from a rectangular panel, which allows visually impressive and multi-dimensional structures. Instructions are available for calculating the capacity of Kerto-Q beam in cases where the face veneer grain direction and the centre line of the member create an angle in relation to one another. There is no limitation on the angle - it can vary between 0 and 90 degrees. The reduction factors are presented in Table 14.

Figure 36: Kerto-Q arches for the roof structure of a windmill. The structure consists of several curved members.

8 Glued components – optimal use of Kerto

The structural gluing of Kerto-Q panels allows large cross-sections that exceed the maximum dimensions of the standard product. Glued Kerto components are CE marked according to a European Technical Assessment (ETA-13/0504), which also includes the basic information for design. A glued component can have a solid rectangular, I-shaped or box cross-section. The maximum production length (20 or 25 metres) and transportation limit the size of glued components. Due to the manufacturing process, members with a cross-section of 144 mm × 1800 mm x 18 m and smaller are easier to manufacture than larger cross-sections.

Kerto-Ripa elements can be manufactured by combining the properties of Kerto-Q panels and Kerto-S ribs. Kerto-Ripa elements create efficient structures by optimally utilizing the properties of Kerto products.

10 Technical details

Kerto products are CE marked according to the harmonized standard of structural laminated veneer lumber EN 14374. The performance levels of products are assessed, and production in the mills is monitored in accordance with Assessment and Verification of Constancy of Performance (AVCP) System 1, which requires continuous surveillance of factory production control by the notified product certification body (VTT Expert Services Ltd.).

*) Kerto-Qp products are suitable for beam applications.

10.1 Panel connections

CE marked fasteners (EN 14592 or ETA) should be used in the connections of load-bearing structures. For non-load-bearing structures, we also recommend the use of CE marked fasteners. Preliminary design tables are presented in the following sections. The capacity of connecting structures should always be designed case-by-case. The preliminary design tables do not replace project-specific structural design by a qualified person.

10.1.1 Fastening panels to vertical or horizontal frames

Connections of Kerto-Q panels can be designed according to EN 1995-1-1 instructions for timber-to-timber connections. Commonly available fasteners can be used in the connections. The connection capacities for panel and fastener combinations for connecting Kerto-Q to Kerto-S, glulam or solid timber frame are presented below.

Table 16: Pre-design table for the lateral load-carrying capacity of **nailed connection** between a Kerto-Q panel and Kerto-S beam/column; load-duration class between instantaneous and medium-term.

| $h^{1)}$ | $d^{2)}$ | $L_{min}^{3)}$ | $\geq a^{4)}$ | $\geq b^{5)}$ | $\geq c^{6)}$ | $R_k^{7)}$ [N] |

Figure 45: Nailed connection of a Kerto-Q panel and glulam or a solid timber beam or column.

Figure 46: Nailing a Kerto-Q roof panel to the frame. Figure 47: Kerto-Q wall panelling.

10.1.2 Wall bracing

Kerto-Q panels serving as diaphragms can be utilized for bracing. Design can be done according to Chapter 9.2.4 of EN 1995-1-1. The following design guidelines are according to 9.2.4.2 Method A.

Information on the national choice for the wall diaphragm design may be found in the National Annex. In Finland, the national choice allows the use of Method A.

There are fewer densely nailed panel joints in the wall diaphragm when 2.4 m wide Kerto-Q panels are used. This speeds up the installation work and reduces the number of fasteners required without reducing the load-carrying capacity.

Preliminary design tables for a single Kerto-Q panel fastened to a wooden frame are presented below. If the wall consists of several panels, the total capacity is the sum of its sectional capacities. The anchoring of the wall diaphragm to the structures below should be designed separately. Wall sections with openings cannot be part of the bracing. The tables are suitable for maximum frame spacing of 2400 mm, although not more than the width of the panel. The capacities are determined for the panel and fastener combinations presented in Chapter 10.1.1.

Table 19: Preliminary design table for characteristic racking load-carrying capacity with **nailed** connections between Kerto-Q bracing panels and a Kerto-S frame. The height of the Kerto-Q panel is 3.0 m; the load-duration class is between instantaneous and medium-term. The distance between the frame studs should not be more than 2400 mm.

| Nail spacing on panel edge on panel centre | | Panel width 2.4 m | c/c150 | c/c100 | c/c75 | Panel width 1.8 m | c/c150 | c/c100 | c/c75 | Panel width 1.2 m | c/c150 | c/c100 | c/c75 |

Figure 48: Principle of wall bracing.

Figure 49: A bracing column made of glued Kerto-Q component.

Figure 50: Example of a wall assembly consisting of several wall panels.

As an example, Figure 48 presents a wall bracing with Kerto-Q bracing panels and Kerto-S or solid wood studs. Due to the large dimensions of Kerto-Q, the stud spacing can be increased. For estimating the minimum thickness of the Kerto-Q panel against the external load $F_{i,v,Ed}$ in service class 2 and in the load-duration class “instantaneous”, the values from Tables 19-21 can be used. According to the tables, the external load for 33 mm Kerto-Q cannot be more than 13.3 kN ($k_{mod} / \gamma_M \cdot F_{i,v,Rk} = 1.1 / 1.2 \cdot 14.6$ kN) when the panel is nailed on the edges c/c 150 mm and in the middle c/c 300 mm using 2.8×70 nails. The capacity can even be doubled if shorter spacing between nails is used.

Kerto-Q panels can be used to build high wall diaphragms. Figure 49 presents a prefabricated Kerto-Q bracing component with a height of around 20 metres. The panel can also be utilized as a column which transfers vertical loads in a four-storey apartment building. It is even possible to brace multi-storey buildings with a single prefabricated component.

Table 22: Comparison table of the racking load-carrying capacity of Kerto-Q panels, softwood plywood and plasterboard with Kerto-S studs. The wall is 2.4 m high and 2.4 m wide; **service class 1**; load-duration class “instantaneous”.

- 1) h [mm] is the thickness of the panel
- 2) $F_{i,v,Rd}$ [kN] is the characteristic racking load-carrying capacity of the wall section
- 3) Diameter and minimum length of the nail ($d \times L_{min}$)
- 4) Fasteners approved by the manufacturer must be used for fastening plasterboard

A comparison of the racking load-carrying capacities of various panel types is presented in the table below. It is possible to achieve higher racking load-carrying capacities with Kerto-Q panels than by using other panel types suitable for similar use. In a typical single-family house, commonly used softwood plywood or plasterboard can brace the building. However, if the building has a large glass wall or bracing walls are sparse or the building is higher than a standard house, Kerto-Q panels are suitable for bracing these types of buildings as well. An example of single-family house bracing wall layout is presented in Figure 50.

Figure 51: Comparison of bracing wall solutions using different materials. All panels are connected with nails and have c/c 100 mm on the panel edges and c/c 200 mm on the panel center. Racking load-carrying capacities are in accordance with Table 23.

10.1.3 Floor and roof bracing

Kerto-Q panels serving as diaphragms can be utilized for bracing. Design for roofs and floors can be done according to Chapter 9.2.3 of EN 1995-1-1. When carrying out preliminary dimensioning, the capacities presented in Chapter 10.1 can be used as the lateral load-carrying capacity for the fasteners.

Information on the national choice for the floor and roof diaphragm design may be found in the National Annex.

10.1.4 Suspended loads

Kerto-Q panels provide an excellent fixing base for various types of fastenings. Self-tapping screws are recommended for axially loaded fastenings as well as axially and laterally loaded fastenings.

The capacity of a suspension connection can be maximised when the threaded part of a screw covers the entire thickness of the point side panel. The preliminary design table for a single tensile-loaded screw is presented below for screws in which the threaded root diameter is 60–75% of the nominal diameter. Fastenings with multiple connectors and/or the capacity of the load-bearing structures should be designed separately.

Figure 52: The maximum allowed suspension load for selected combinations of Kerto-Q panels and connectors.

Table 24: Pre-design table for a single tensile-loaded screw in a Kerto-Q panel.

| $h_{min}^{1)}$ | $l_{ef,min}^{2)}$ | Screw | $F_{ax,Rk}^{3)}$ [kN] | $F_{ax,all}^{4)}$ [kg] |
|----------------|-------------------|-------|-----------------------|------------------------|
| 21 | 21 ¹⁾ | 5 | 1.91 | 72 |
| 24 | 24 ¹⁾ | 5 | 2.12 | 80 |
| 27 | 27 ¹⁾ | 5 | 2.33 | 88 |
| 33 | 30 | 5 | 2.54 | 95 |
| 39 | 36 | 6 | 3.66 | 138 |
| 45 | 40 | 6 | 3.98 | 150 |
| 51 | 50 | 6 | 4.76 | 179 |
| 63 | 60 | 6 | 5.50 | 207 |
| 63 | 60 | 8 | 8.18 | 308 |

1) h_{min} [mm] is the minimum thickness of the Kerto-Q panel

2) $l_{ef,min}$ [mm] is the minimum penetration depth of the threaded part in a Kerto-Q panel, ¹⁾the narrowed tip must penetrate through panel completely

3) $F_{ax,Rk}$ [kN] is the characteristic load-carrying capacity of the suspension connection

4) $F_{ax,all}$ [kg] is the permitted load for the suspension connection (service class: 1, load-duration class: permanent, $k_{mod} = 0.6$ and $\gamma_M = 1.2$).

All general connector types can be used in laterally loaded connections of Kerto-Q panels. These include nails, screws, dowels and bolts. The panel can be located on the head or point side of the fastener. The preliminary design table for various lateral screw connections is presented below. The table can be applied for self-tapping screws when the threaded root diameter is 60-75% of the nominal diameter. Fastenings with multiple connectors and/or the capacity of the load-bearing structures should be designed separately.

Figure 53: The maximum allowed suspension load for selected combinations of Kerto-Q panels and connectors.

Table 25: Pre-design table for a single laterally loaded screw in a Kerto-Q panel.

| $h_{min}^{1)}$ | $l_{ef,min}^{2)}$ | Screw | $F_{v,Rk}^{3)}$ [kN] | $F_{v,all}^{4)}$ [kg] |
|----------------|-------------------|-------|----------------------|-----------------------|
| 21 | 21 ¹⁾ | 5 | 0.76 | 28 |
| 24 | 24 ¹⁾ | 5 | 0.87 | 32 |
| 27 | 27 ¹⁾ | 5 | 0.89 | 33 |
| 33 | 30 | 5 | 1.08 | 41 |
| 39 | 36 | 6 | 1.48 | 56 |
| 45 | 40 | 6 | 1.65 | 62 |
| 51 | 50 | 6 | 2.06 | 77 |
| 63 | 60 | 6 | 2.11 | 79 |
| 63 | 60 | 8 | 3.02 | 114 |

1) h_{min} [mm] is the minimum thickness of the Kerto-Q panel

2) $l_{ef,min}$ [mm] is the minimum penetration depth of the threaded part in a Kerto-Q sheet, ¹⁾the narrowed tip must penetrate through the panel completely

3) $F_{ax,Rk}$ [kN] is the characteristic load-carrying capacity of the suspension connection

4) $F_{ax,all}$ [kg] is the permitted load for the suspension connection (service class: 1, load-duration class: permanent, $k_{mod} = 0.6$ and $\gamma_M = 1.2$)

Figure 54: Sprinkler pipes and nozzles suspended from a Kerto-Q panel.

Figure 55: Ventilation ducts suspended from a Kerto-Q panel.

The combined lateral and axial load-carrying capacity can be calculated according to standard EN 1995-1-1 using the equation (8.27) for smooth nails and equation (8.28) for screws and threaded nails. Figure 56 can be used for checking the combined capacity for screws in accordance with preliminary design Tables 24 or 25.

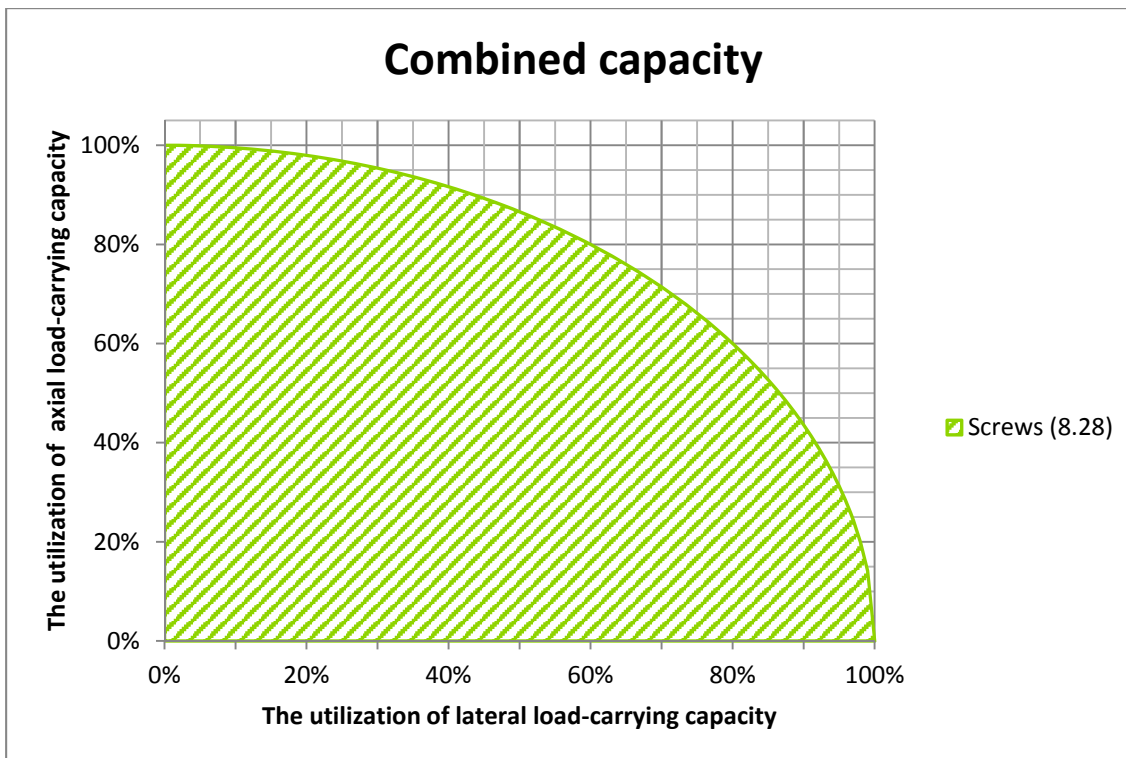

Figure 56: Combined capacity of laterally and axially loaded screws.

11 Protective treatments

Kerto products can be protected using various surface treatments. Surface treatments can be applied at the mill for Kerto products with a maximum width/height of 900 mm and a maximum length of 15 m. Check the availability of larger treated panels from the local sales office.

Kerto WeatherGuard - temporary protection against rain during construction

Figure 57: WeatherGuard treated Kerto LVL.

The WeatherGuard treated surface is resistant to rainwater and reduces the absorption of water in Kerto products. At the same time, the surface allows the panel to breathe and water vapour to move freely to and fro. The reduced absorption of water reduces moisture deformations of Kerto LVL, which improves the dimensional stability and decreases the time and energy needed for drying the structures. The treatment provides temporary protection during storage and construction. If long-term protection is needed, the wooden surface can be coated with paints, lacquers, varnishes and protection treatments applicable on wood products. It is recommended that the applicability of the coating is confirmed by the treatment supplier.

Kerto WeatherGuard is suitable for use in service classes 1 and 2. The treatment has no effect on the strength properties of Kerto; nor does it have an effect on reaction to fire, resistance to fire, and slip resistance of the surface. Furthermore, the treatment has no effect on the corrosion resistance of the metal fasteners used in the connections. The colour of WeatherGuard treatment is transparent and it does not contain biocides.

The moisture content of WeatherGuard treated product remains lower than untreated products. In addition, the risk of damage caused by moisture-affected structures decreases. WeatherGuard treated products can be disposed of in the same way as untreated wood products since they do not contain environmentally harmful substances. Kerto WeatherGuard has the Finnish M1 emissions classification for building materials, as does untreated Kerto LVL. Formaldehyde emissions for both treated and non-treated products are far below the class E1 requirements.

Kerto MouldGuard - reduces the risk of mould growth on surfaces

Kerto MouldGuard is surface impregnated with a wood protective agent. It significantly reduces the risk of surface mould compared to untreated Kerto LVL. Kerto MouldGuard is ideal for structures in unheated spaces, as load-bearing roofing panels and in ventilated floor structures. The product has a light orange colour and the surface can be further treated with standard paints, lacquers and varnishes applicable on wood products. It is recommended that the applicability of the coating is confirmed by the treatment supplier.

Kerto MouldGuard is suitable for use in service classes 1 and 2. The treatment has no effect on the strength properties of Kerto; nor does it have an effect on reaction to fire, resistance to fire, and slip resistance of the surface. Furthermore, the treatment has no effect on the corrosion resistance of the metal fasteners used in connections. Kerto MouldGuard has the Finnish M1 emissions classification for building materials and formaldehyde emissions are far below the class E1 requirements. Direct contact with foodstuffs, animal feed or similar must be avoided.

Kerto MouldGuard can be considered as biofuel (EN 14961-1) and it can be safely burnt when the combustion temperature is at least 850°C and correct combustion conditions are maintained. Due to preservative treatment, the correct combustion conditions and suitable waste burning plants should be checked locally.
